Experiment No. 14: Pro-Code Extension Using Zoho Catalyst

1. AIM

To study how Zoho Catalyst extends low-code applications using pro-code development and serverless technologies.

2. THEORY

Zoho Catalyst is a cloud-based development platform that enables developers to build, deploy, and manage applications using programming languages and cloud services. It extends low-code platforms by supporting custom logic, backend services, APIs, and advanced application features.

Key features include:

- **Serverless Functions:** Execute custom backend code without managing servers.
- **API Integration:** Connect applications with external services.
- **Database Services:** Store and manage application data.
- **Authentication:** Manage user identity and access.
- **Cloud Deployment:** Deploy application components to the cloud.
- **Custom Logic:** Implement complex features beyond standard low-code capabilities.

3. PROCEDURE

1. Sign in to the Zoho Catalyst platform.
2. Create a new project in the Catalyst console.
3. Select a suitable project type and configure the development environment.
4. Create a serverless function using a supported programming language.
5. Write custom logic to process application data.
6. Configure the required database or API integration.
7. Test the function using sample input.
8. Deploy the function and verify its execution.
9. Integrate the function with a Zoho Creator application, if required, using an appropriate API or connection.

4. APPLICATION

In a Vehicle Service Management System, Zoho Creator can manage service request forms and reports, while Zoho Catalyst can handle advanced backend processing, external API integration, and custom notifications.

5. RESULT

The use of Zoho Catalyst for pro-code extension was studied. It enables low-code applications to support advanced functionality through custom programming, serverless functions, APIs, and cloud services.
